The following qualitative data were collected by trained interviewers from diverse demographic backgrounds:

- Semi-structured in-depth interviews with 75 patients (aged 14-72) from 14 sites randomized to the FI intervention (all patients received at least 1 FI).
- Key informant interviews with 92 site investigators (58% mostly clinicians) [6 BN; 6 DC] from 51 sites randomized to the FI intervention.

Interviews were conducted in English, audio-recorded and transcribed. Transcripts were coded for major themes and analyzed in NVivo 10.0. Sub-themes related to conceptual understanding of VL and its relationship to ART adherence were extracted and examined.

Clinical data were also collected to determine patients’ VL suppression status during the study. VL suppression status was compared to qualitative understanding of VL to explore potential relationships.
